

Sampling of *Phytophthora infestans* and *Ralstonia* spp. from wild *Solanum*

OBJECTIFS

The goal of this project is to establish a database with pathogen samples from four diverse wild tomato species (each with unique habitats) for further studies into pathogen diversity and adaptation.

ACTIONS

This exploratory project encompasses one major sampling trip for two devastating tomato (and potato) pathogens, the oomycete *Phytophthora infestans* and the bacterial species complex *Ralstonia solani* (RSSC). Sampling will take place in November/December 2017 and will span three geographical regions in Peru. 1. Central : Lima, 2. North : Chiclayo/CajaMarca 3. South: Arequipa/Tacno. Together with the Peruvian Partners at CIP, we will extract DNA from all samples from both pathogens and prepare the samples for long term storage. Genotyping for both pathogens will be done in Europe PVBMT (RSSC), GAFL/TUM (*Phytophthora infestans*).

RESULTATS

At the end of this projects we will have gained insights in the global diversity of two major tomato pathogens. With our genotyping data we can see which patterns occur in both species and if these unrelated pathogens show similar (or in fact dissimilar) genetic clustering and if and how this relates to the different host species as well as climatic variables.

PERSPECTIVES

The initial results will form the basis for more detailed population genetics studies as well as molecular studies to unravel which genes are involved in different adaptations and how these genes can be utilised in future breeding programmes.

In light of global climatic changes, understanding the link between pathogen – host and climate adaptation will be of utmost importance to mitigate future disease epidemics.
